## POLYETHYLENE TECHNICAL PROPERTIES

$\begin{array}{|l|c|c|c|c|c|}$\cline { 2 - 5 } \& Specification \& Units \& $\left.\begin{array}{c}\text { High density } \\ \text { PE MRS 6.3 }\end{array} & \begin{array}{c}\text { Middle density } \\ \text { PE MRS 8 }\end{array} \\ \hline \text { Mechanical properties polymer } \\ \text { PE MRS 10 }\end{array}\right]$

## The above values are indicative.

According to ISO 9080, the minimum required strength (MRS) is the value of long-term hydrostatic strength with a lower limit of confidence of $97.5 \%$ shown by one pipe after 50 years of constant work at $20^{\circ} \mathrm{C}$.

1 = Good resistance
2 = Moderate resistance
3 = Not recommended
w.s. = water solution with concentration higher than 10\%,
l.w.s. = water solution low concentration (under 10\%)
s.s. = saturated solution
l.c. = low concentration
h.c. = high concentration
$\% \quad=$ weight percentage

This information concerns only ordinary chemical resistance. When giving an account of other factors like resistance to cracking due to load, conductivity and others, it is necessary to put to specific tests for compatibility.

## COMPOUND FOR PRODUCTION OF PE100 PRESSURE PIPES

Compound from which polyethylene water pipes are being produced must be preliminary colored in the color of the final product according to the
production standard BDS EN 12201-1. If pipes must be black compound is black. If they must be blue compound is blue and so on. Standard BDS EN12201-1

FORBIDS the usage of colorless (natural) PE compound in production of polyethylene water pipes.

Only preliminary colored compound guarantees a homogeneous structure of the produced pipes, good longtime pressure resistance and good elasticity
of the material.
The usage of a colorless compound and its sequential coloring during the production causes bad homogeneity
of the material, which can be seen only with microscope:

Good homogeneous structure of a pipe produced from preliminary colored compound.

Bad heterogeneous structure of a pipe produced from preliminary colored compound.

The quality of the PE pipe is deteriorated due to bad homogeneity. This leads both to substantial reduction of the operational life of the pipe and to eventual bursting of the pipe. Such pipes
cannot bear the laboratory tests for internal hydrostatic pressure and tensile stress, which basically depend on the material that is used for the production of the pipe.

In some rare cases mixing of the pigment and the compound during the extrusion is so bad that separated layers in the pipe cross-section could be noticed with the naked eye.

Some producers buy colorless compound and after that they color it during the extrusion because in this way they save money (the colorless compound is cheaper than the preliminary colored compound). They gain lower price by worsening quality and safety.
Pipelife Bulgaria EOOD is producing its own polyethylene pipes entirely from VERGIN AND CERTIFIED COMPOUND from established manufacturers of
the international market like "Sabic", "Borealis", "Basell" and "Ineos". These manufacturers guarantee CONSTANT high quality of their compound. Each delivery of polyethylene compound in the factory in Botevgrad comes with a Quality Certificate issued by the manufacturer of this compound. Our laboratory staff takes 50 grams of polyethylene compound and tests a certain part of that quantity and the rest
part of the sample is conserved for six months.

The material for production of polyethylene pipes for water and gas is preliminary colored high density polyethylene (PE100). The PE water pipes are produced in black color with blue stripes.

| 1750 | 0.90 | 0.92 |

## WATER HAMMER

Water hammer is an inconstant effect caused by rapid changes of flow conditions. The water hammer is passed on as a wave which leads to brief pressure changes. The water hammer can damage the network or the
control and measurement instruments especially at high values of flow change. In this case the pipe is under the influence of considerable pressure increases and decreases (excess pressure or subpressure) in relation to
the normal one. The network length, the short duration of the transitional influence (for example very fast closing of a valve) and the turning on and off of pumps or water turbine are the most common reasons for the problem.

For every network there is a constant
Where

| = pipe's length |
| :--- |
| a $=$ velocity of the pressure wave in the pipe |

$\mathbf{a}$

The hydraulic shock or if we have to be more accurate the creation of high excess pressure or subpressure in the pipe network appears when the time (t) of the transitional influence, which generates the flow state change, is shorter than the network time constant (T):

## t < T

The water hammer can be described with the help of Figure 1.
Let's examine a pipeline with a length I, in which flows liquid from a reservoir with big dimensions, situated at point $A$. It is accepted that the flow is not influenced by the friction and that at the moment $\mathrm{t}=0$ a instantaneous closing of a valve is made at the end of the pipe, point B.

At point $B$ appears excess pressure ( P ) which passes along the pipe as a wave with velocity called wave velocity (a), determined by the pipe and fluid's properties. When after time $t=T / 2$ the pressure reaches point $A$, the whole pipeline is under the influence of excess
pressure (P). Due to the fact that the condition is not stable, the wave caused by the pressure is reflected by the reservoir. Thus a back wave is created which passes along the pipe with the same velocity (a) and when it reaches point $B$ at the moment $t=T$ it restores the pipeline pressure to its initial value. At this moment the kinetic energy of the flowing fluid transforms into potential energy and the pressure falls. This pressure change (subpressure - P), caused by the energy transformation, passes along the pipeline to point $A$. At the moment $t=3 T / 2$, the pressure change reaches point $A$ and the whole pipeline is under the influence
of subpressure (-P). This situation is unstable, the subpressure wave reflects in the reservoir and a pressure change appears in the opposite direction, as it restores the pipeline pressure to its initial value. At the moment $t=2 T$ the pressure change has reached the valve and the pressure of the fluid along the pipeline is in its initial value. It is the same situation as at the moment $t=0$ and if there are no energy losses, the process would continue to repeat. But in practice, energy losses exist like fluid friction, while the pressure changes disappear after a few cycles.
On Figure 1 we see three-dimensional representation of this effect.

Figure 1
The rapid changes of the basic velocity and of the water in the pipe lead to increase in the pressure which is defined by the following formula for a flow without friction:

$$
\Delta \mathrm{P}=\frac{\alpha \cdot \Delta \mathrm{u}}{\mathrm{~g}}
$$

## Where

$\Delta P=$ overpressure ( $m$, of water column)
a = wave velocity ( $\mathrm{m} / \mathrm{sec}$ )
$\Delta u=$ change in the basic velocity ( $\mathrm{m} / \mathrm{sec}$ )
$g=$ gravity acceleration ( $9.81 \mathrm{~m} / \mathrm{sec}^{2}$ )

The wave velocity is defined by the following formula:

$$
\alpha=\sqrt{\rho\left(\frac{1}{k}+\frac{D \cdot C}{E \cdot S}\right)}
$$

Where
a = wave velocity ( $\mathrm{m} / \mathrm{sec}$ )
$\rho=$ fluid density $\left(\mathrm{kg} / \mathrm{m}^{3}\right)$
$\mathrm{k}=$ coefficient of contractibility $\left(\mathrm{N} / \mathrm{m}^{2}\right)\left(\mathrm{k}_{\text {water }}=2 \cdot 10^{9} \mathrm{~N} / \mathrm{m}^{2}\right)$
$\mathrm{E}=$ модул на еластичност на стената на тръбата (N/m2)
$\mathrm{s}=$ thickness of the pipe wall (m)
$D=$ internal diameter (m)
c = coefficient, depending on the way of pipe's installation
coefficient of lateral shrinkage $v$ (Poisson's coefficient)

The overpressure, calculated according to the above formulae is the maximum possible overpressure (or subpressure).

When transitional effect lasts longer than $T(t>T)$, overpressure is calculated by the formula:

$$
\Delta \mathrm{P}=\frac{2 \mathrm{~L}}{\mathrm{~g}} \cdot \frac{\Delta \mathrm{u}}{\mathrm{~T}}
$$

and depends on the pipe's length.
In Table 1 are given the modulus of elasticity of some conventional materials for pipe.

## TABLE 1

MODULUS OF ELASTICITY OF CONVENTIONAL MATERIALS FOR PIPES

| MATERIAL | MODULUS OF ELASTICITY <br> $\left(\mathbf{N} / \mathbf{~ m}^{2}\right)$ |
| :---: | :---: |
| PVC-U | $3 \cdot 10^{9}$ |
| MDPE (PE 80) | $6.5 \cdot 10^{8}$ |
| HDPE (PE 100) | $1.4 \cdot 10^{9}$ |
| Steel | $2.1 \cdot 10^{11}$ |
| Cast iron | $1.6 \cdot 10^{11}$ |
| Asbestos | $1.9 \cdot 10^{10}$ |

It must be mentioned that the plastic pipes have a certain capability to withstand the pressure which exceeds the pressure of
the class i.e. the nominal pressure. In case of often water hammers occurrences in a pipeline, the pipes are influenced by
pressures which are above the nomina values, for which they are designed. Under these conditions i.e. when

$$
\Delta \mathrm{P}+\text { pipeline work pressure }>\text { pipe nominal pressure, }
$$

the consequences with regard to the pipe's strength are very important. Due to this reason, in cases when the water hammer effect appears, it is recommended the pipeline to be
designed by giving an account to the fact that the sum of the work pressure and the overpressure, caused by the water hammer, must be lower than the nominal pressure of the used pipes.

The following diagrams represent the overpressure as a result of the water hammer in pipes, made from:

- PE 100 (third generation), according to EN 12201-2
- PE 80 (second generation), according to EN 12201-2

## DIAGRAMS OF EXCESS PRESSURE AS A RESULT OF WATER HAMMER

PE 100 PRESSURE PIPES, EN 12201-2 and DIN 8074-8075

PE 80 PRESSURE PIPES, EN 12201-2 and DIN 8074-8075

## CALCULATION OF PLAST PIPES DEFLECTIONS

For the calculation of plastic pipe deflection under the soil pressure with which it is covered, the following procedure is observed.

## Calculation of the soil static pressure, Ps (Figure 2)

Figure 2

## $P s=c \cdot \gamma \cdot H$

and

$$
c=\frac{1-e^{-2 \cdot k \cdot \varepsilon \varphi \delta \cdot H / W}}{2 \cdot k \cdot \varepsilon \varphi \delta \cdot H / W}
$$

## Where

Ps = soil pressure over the upper part of the pipe $\left(\mathrm{kg} / \mathrm{m}^{2}\right)$
$y=$ soil specific weight ( $\mathrm{kg} / \mathrm{m} 3$ )
$H=$ depth of the cover (m)
W = trench width (m)
$c=$ coefficient of pressure according to the soil type
$\mathrm{k}=$ coefficient related to the vertical and horizontal pressure
$\delta=$ angle of friction of the filling material (bedding angle)
The values of $k$ and $\delta$ are taken from Table II.

TABLE II

| Properties of the material for filling the trenches | $\mathbf{K}$ | $\delta($ Table IV) |
| :--- | :---: | :---: |
| - The material for filling is compacted to a certain degree | 0.5 | $\delta=\rho$ |
| - There is a trench |  |  |
| - The material for filling is not compacted enough |  |  |
| - Vertical walls of the trench are set up for support of the soil |  |  |
| - There are underground waters | 0.5 | $\delta=2 / 3 \rho$ |
| - The material is compacted enough <br> dense soil $D p>95 \%$ <br> crumbly soil $D p>97 \%$ |  |  |

## Calculation of traffic load, Pw (Figure 3)

Figure 3

It is recommended in all cases the cover layer to be deeper $(\mathrm{H})$ than 0.8 m .
The following formula is not valid for $\mathrm{H}<0.5 \mathrm{~m}$.

## Where

$$
\mathrm{P}_{\mathrm{w}}=\frac{3 \cdot \mathrm{P}}{2 \cdot \pi \cdot \mathrm{H}^{2}\left\{1+\frac{\mathrm{x}^{2}}{\mathrm{H}^{2}}\right\}^{5 / 2}}
$$

P = car's weight (kg)
$\mathrm{X}, \mathrm{H}=$ distances in m , as shown on Figure 3 (m).

## Total load

The total load $(q)$ is calculated with the formula:

$$
\mathrm{q}=\mathrm{Ps}_{\mathrm{s}}+\mathrm{P}_{\mathrm{w}} \mathrm{~kg} / \mathrm{m}^{2}=\mathrm{q} / 10000 \mathrm{~kg} / \mathrm{cm}^{2}
$$

If the pipe is ideally buried on the trench bottom and if the soil filled in laterally, above and at the ends is well compacted, only part of the load influences the pipeline walls. That is why the formula changes as:

$$
\mathrm{qr}=0,5 \cdot \mathrm{q}=\mathrm{qr} / 10000 \mathrm{~kg} / \mathrm{cm}^{2}
$$

## Calculation of the pipe's section stiffness, Rt

$$
\mathrm{Rt}_{\mathrm{t}}=\frac{2 \cdot \mathrm{E} \cdot \mathrm{~s}^{3}}{3(\mathrm{Dn}-\mathrm{s})^{3}}
$$

## Where

Dn = pipe's nominal diameter (cm)
$\mathrm{s}=$ pipe's thickness (cm)
$\mathrm{E}=$ modulus of elasticity $\left(\mathrm{kg} / \mathrm{cm}^{2}\right)$

TABLE III
Modulus of elasticity

| Et | uPVC | PE 80 (2-u) | PE 100 (3-u) |
| :---: | :---: | :---: | :---: |
| Long-term elasticity | 30000 | 6500 | 14000 |
| Short-term modulus | 20000 | 1650 | 3500 |

## Calculation of soil stiffness, Re

$$
\mathrm{Re}=0,6 \cdot \mathrm{e} \cdot \mathrm{Ee}
$$

Where
e = coefficient for correction
$\mathrm{Ee}=$ modulus of elasticity, second modulus of the surrounding burying material (Table IV)

TABLE IV
Modulus of elasticity of the soil around the pipe

| Soil group (according to ATV) | Specific weight $\underset{\left(\mathrm{gr} / \mathrm{cm}^{3}\right)}{\mathrm{V}}$ | Angle of friction$\underset{\left({ }^{\circ}\right)}{\rho}$ | Ee ( $\mathrm{kg} / \mathrm{cm}^{2}$ ), Depending on |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | 85\% | 90\% | 95\% | 97\% | 100\% |
| Crumbly soil, big granules (gravel) | 2 | 35 | 25 | 60 | 160 | 230 | 400 |
| Lightly compacted soil, fine granules (sand) | 2 | 30 | 12 | 30 | 45 | 80 | 200 |
| Dense mixed soil, slime (sand and gravel) | 2.1 | 25 | 10 | 20 | 30 | 60 | 160 |
| Dense soils (clay) | 2 | 20 | 6 | 15 | 20 | 40 | 100 |

Calculation of the system stiffness (pipe's section-surrounding soil), Rs

$$
R_{s}=\frac{R_{t}}{R_{e}}
$$

## Calculation of pipe's deflection, Dn and Def

$$
\begin{array}{lll}
\Delta \mathrm{Dn}=\frac{\mathrm{q} \cdot}{} \cdot \mathrm{Dn} \\
2 \mathrm{R}_{\mathrm{t}} & \xi & \text { and } \\
\mathrm{L}=\frac{0,083}{\mathrm{R}_{\mathrm{s}}+0,066} & \text { and } & \text { Def }=\frac{\Delta \mathrm{Dn}}{\mathrm{Dn}} \cdot 100 \%
\end{array}
$$

Where
$\Delta \mathrm{Dn}=$ diameter change (cm)
Def = deflection (\%)

## An example of deflection calculation

Sewer pipes PE 1000400 (thickness 14 mm ) are buried in the ground at the depth of 2.6 m , in a trench which is 1
m . wide. The trench is filled with lightly compacted gravel ( $\mathrm{Dp}=90 \%$ according to Proctor). The soil specific weight is =
$2000 \mathrm{~kg} / \mathrm{m}^{3}$ and the angle of friction is p $=35 \%$. The load of the passing vehicles is 30.000 kg .

## Calculation of the static pressure of the soil, Ps

$$
c=\frac{1-e^{-2 \cdot 0.5} \cdot \varphi \varphi 35 \cdot 2.6 / 1}{2 \cdot 0,5 \cdot \varepsilon \varphi 35 \cdot 2,6 / 1}=0,46
$$

and

$$
P_{\mathrm{s}}=0,46 \cdot 2000 \cdot 2,6=2393,75 \mathrm{~kg} / \mathrm{m}^{2}
$$

## Calculation of the traffic load

$$
P_{w}=\frac{3 \cdot 30,000}{3 \cdot \pi \cdot 2,6^{2}}=2,120 \mathrm{~kg} / \mathrm{m}^{2}
$$

$$
\begin{gathered}
\mathrm{q}=2,393+2,120=4,513 \mathrm{~kg} / \mathrm{m}^{2}=0,4513 \mathrm{~kg} / \mathrm{cm}^{2} \\
\mathrm{qr}=\mathrm{q} \cdot 0,5=0,2256 \mathrm{~kg} / \mathrm{cm}^{2}
\end{gathered}
$$

## Calculation of the pipe's section stiffness, Rt

$$
\mathrm{R}_{\mathrm{t}}=\frac{2 \cdot 3,500 \cdot 1,4^{3}}{3 \cdot(40-1,4)^{3}}=0,111
$$

## Calculation of the soil stiffness, Re

$$
\mathrm{Re}=0,6 \cdot 1 \cdot 60=36 \mathrm{~kg} / \mathrm{m}^{2}
$$

## Calculation of the system stiffness (soil - pipe), Rs

$$
R s=0,111 / 36=0,0031
$$

## Calculation of pipe's deflection, $\Delta \mathrm{Dn}$ and Def

$$
\begin{array}{cc}
L=\frac{0,083}{0,00031+0,066}=1,201 & \xi=-0.166+0.128 \cdot L=-0.012 \\
\Delta \mathrm{Dn}=\frac{0,2256 \cdot 40}{2 \cdot 0,111}(-0,012)=0,488 \mathrm{~cm} & \text { Def= } \frac{0,488}{40} 100=1,22 \%
\end{array}
$$

## STRENGTH AT LONGITUDINAL BENDING OF PIPES UNDER THE INFLUENCE OF EXTERNAL HYDROSTATIC PRESSURE

The external pressure for example of the soils and of the underground waters creates contraction forces around the pipe's wall. When the contraction forces
around the pipe's walls exceed a certain limit, it is possible the elliptical deformed pipe to crumple due to the bending of the wall.

The theoretical resistance to longitudinal bending $(\mathrm{Pb})$ is calculated according to the following equation:

## And because

$$
\mathrm{I}=\frac{\mathrm{s}^{3}}{12}
$$

$$
P_{b}=\frac{24 \cdot E \cdot \mid}{\left(1-v^{2}\right) \cdot D_{m}^{3}}
$$

$$
\mathrm{P}_{\mathrm{b}}=\frac{2 \cdot \mathrm{E}}{\left(\mathrm{I}-\nu^{2}\right)}\left(\frac{\mathrm{s}}{\mathrm{D}_{\mathrm{m}}}\right)^{3}
$$

Where
$\mathrm{Pb}=$ load with longitudinal bending $\left(\mathrm{kgf} / \mathrm{cm}^{2}\right)$
$\mathrm{E}=$ modulus of elasticity of pipe's material ( $\mathrm{kgf} / \mathrm{cm}^{2}$ )
$\mathrm{s}=$ wall thickness (cm)
Dm = average diameter of the pipe (cm)
$\nu=$ coefficient of Poisson

The formula validity depends on the pipe's elasticity and circumference. If the pipe has deflections and elliptic shape,
then the load with longitudinal bending Pb must be corrected with a coefficient whose value, according to the pipe's
deflection, is taken from Diagram 1.

DIAGRAM 1

When the pipe is buried in the ground, it touches the surrounding soil. If the soil is well compacted and
has a high modulus of elasticity, then the pipe's support is considerable and must be taken into account by using
the coefficient fs, which is taken from Diagram 2 in accordance with the work pressure of the pipe.

DIAGRAM 2

That is why when we lay a pipe in the ground, we have the following:

## P'b=Pb•fov•fs

The pipes which are submerged at the depth Hw, are under the influence of external (hydrostatic) pressure, calculated according to the following formula:

$$
P_{w}=\frac{\gamma_{w} \cdot H_{w}}{10,000}
$$

Where
Pw = external (hydrostatic) pressure (kgf/m²)
yw = specific weight of water (kgf/m³)
Hw = water depth above the pipe (m)

With the help of the safety coefficient $(S=2)$ we can calculate the maximum depth (Hwmax), at which the pipe can work reliably.

$$
H_{w \max }=\frac{10,000 \cdot \mathrm{P}_{\mathrm{b}}^{\prime}}{2 \cdot \gamma}
$$

# POLYETHYLENE PIPES TRANSPORTATION AND STORAGE 

To preserve their technical properties the polyethylene pipes must be used,

## A. TRANSPORTATION

- The pipes must be transported in suitable vehicles with smooth inner surface which doesn't allow the damage of the pipes.

## B. STORAGE

- During the storage the pipes must not be bended or damaged. Such problems are possible if the pipes are not arranged properly to a certain height. The pipes must not be arranged standing and one over other higher than 1.5 m , and the areas for storage must be
transported and stored in accordance with the following instructions.
- The pipes must not be pulled over the surfaces of the vehicle, must be properly loaded, put one over other on smooth surfaces and unloaded. If the pipe's wall
smooth without stones and other sharp objects along the pipe. If the pipes are manufactured with fittings, the fittings must be sticking out.
- The pipes with different diameters must be stored separately. If this is impossible, the pipes with bigger
has a scratch, deep $10 \%$ of the wall's thickness, it is recommended this part to be replaced.
diameter must be stored at the bottom of the package.
- When the pipes are stored for a long period, spirally rolled, they must be stored horizontally.

## POLYETHYLENE PIPES INSTALLATION

## A. UNDERGROUND NETWORKS

Compared to the conventional, the polyethylene pipes can be buried in trenches with smaller dimensions. The long, butt welded pipes, connected

The trench depth must exceed:

- 50 см for roads without traffic;
- 60 см for roads with poor traffic;
- 80 cm for roads with normal or busy traffic.

The trench width can be as small as possible but not smaller than the pipe's diameter plus 20 cm in order to allow proper compacting of the lateral filling material and proper distribution of the

## B. ABOVE-GROUND NETWORKS

Using of above-ground networks allows utilizing of the inherent properties and characteristics of the material as resistance to deterioration from sunlight, good resistance to impacts even at low temperatures, big flexibility and others.
above ground, can be buried in narrow trenches, after being left to cool. In principle the dimensions of the trenches are defined according to the diameter of
the pipes, the method of connection and the soil type.
which provides an even support of the buried polyethylene pipe. If it has no stones the dug soil can be used as a lateral material for filling.

- Providing of supports for the pipelines at certain intervals, especially for the parts with heavy fittings (for example valves).

## C. SUBMERGED NETWORKS

The decision for burying underground and the responsibility for this procedure execution depend totally on the subcontractor and most of all on the means which he has. The work site must be smooth and close to the bank. If the pipes are delivered rolled on spiral,

## D. RADIUS OF BENDING

At normal temperatures the polyethylene pipes can be bended to a radius Rs, which is equal to 12-20 times their external diameter (DIN 16933). The inherent flexibility of the polyethylene pipes allows being avoided significant
enough space must be provided (at least 100 m ) for their unwinding.
The polyethylene density is lower than $1 \mathrm{gr} / \mathrm{cm} 3$. Due to this the pipes must be buried with additional weights (ballast), which hold the pipes steady on the sea bottom. The weights are made of
number of fittings during the design and building of pipeline system. If the pipes are delivered rolled on spiral or on spools, they must be bended at the direction of winding.
concrete (armored or not) and can be in different shapes. To avoid damaging of the external surfaces of the pipes from the concrete weights, usually the latter are coated with soft material (for example polyethylene foil).

## POLYETHYLENE PIPES CONNECTION

## A. WELDING

Polyethylene can be welded. Welding is a process of thermal connecting by heating to $220^{\circ} \mathrm{C}$ of the surfaces of the circle openings of the connected polyethylene pipes until reaching a state of melting of every contact surface. After that the two surfaces are joined under controlled pressure for a certain period for cooling and by joining the molecules of the two pipes a homogeneous welding
is achieved.

- The spots for joining are resistant to axial pressure and under pressure their strength can be compared with the pipe's one.
- Polyethylene pipes flexibility and the flexibility of the joining allow the designer to connect the pipes on the ground surface and after that to bury them in the trench, regardless of the
used burying technique.
- Continuity and smoothness of the internal surface of the pipes are preserved and the coefficient of roughness ( $k$ ) is not increased. Even if it is necessary the stripe which is formed as a result of the welding can be easily removed.

## 1. BUTT WELDINGE

For the butt welding of polyethylene pipes a special welding machine is necessary with heating plate ("mirror") for heating the pipe's end to melting point which later on are connected under pressure. The principle sequence of the welding procedure is illustrated on Figure 4.

- The pipes' ends, tightened up in the welding machine, are made smooth with the help of a smoothing device. In this device the pipe's ends are checked for axial alignment.
- The pipes' ends are pressed towards the heating element with the necessary pressure $P$ for smoothening until the moment when the joining surfaces are melted all around their circumference and on the internal and the external parts of the pipes a stripe is formed which 2 mm high.
- The pressure for aligning is reduces almost to zero and the time for heating begins to go by. The heating without pressure continues until the melting of the necessary polyethylene mass
around the heated area.
- The pipes' ends are released from the heating element which is removed without touching the fusion surfaces and then immediate connecting of the pipes is made under welding pressure $P$. - The welding pressure $P$ is maintained during the whole period of cooling.
The time for cooling, the heating pressure and the welding and the height of the formed welding stripe depend on the parameters of the welded pipes (diameter, wall thickness).

Figure 4

## 2. FUSION WELDING

During the fusion welding it is required a special aggregate for welding control, which sends heat energy (direct current) towards the special polyethylene fitting for melting.
The fitting is a connecting device with

## B. MECHANICAL CONNECTION

The mechanical connection of polyethylene pipes is achieved by appropriate mechanical fittings. They
two nests with a heating element (wire), formed along the surface for welding at the joining points. When the two leveled ends of the pipe are inserted into the device and electricity is applied, the heat, generated at the element welds together
the joined surfaces. The time for welding and the application of electricity, which depend on the diameter and the fitting type, are regulated manually or automatically by a control panel.
are made of different materials (plastic and metal) and are two types:

- Fittings for multiple uses which can be
taken off the pipe and used again.
- Permanently mounted fittings which cannot be taken off the pipe.

## BUTT WELDING <br> WELDING PRESSURE (Kр)

Manometer readings (bar) = welding force /f*
*The coefficient f is usually indicated by the manufacturer of the machine, with usual value $1 \mathrm{bar}=\mathrm{fK}$.

## UTT WELDING: TIME OF HEATING AND COOLING

Again the total time for butt welding is determined to a great extend by the time for preparation i.e. the time necessary for:

- Joining the pipes
- Leveling
- Providing of axial alignment
- Cleaning

It is obvious that properly prepared work site and the welders' experience play a significant role for the total time, necessary for the butt welding procedure.

Note: The time for cooling varies according to the temperature of the environment.
